

Programming with Databases

- Programming with Databases
- PL/DB Interface
- PL/DB Mismatch

❖ Programming with Databases

So far, we have seen ...

- accessing data via SQL queries
- packaging SQL queries as views/functions
- building functions to return tables
- implementing assertions via triggers

All of the above programming

- is very close to the data
- takes place inside the DBMS

❖ Programming with Databases (cont)

While SQL (+ PLpgSQL) gives a powerful data access mechanism

- it is *not* an application programming language

Complete applications require code to

- handle the user interface (GUI or Web)
- interact with other systems (e.g. other DBs)
- perform compute-intensive work (vs. data-intensive)

"Conventional" programming languages (PLs) provide these.

We need PL + DBMS connectivity.

❖ Programming with Databases (cont)

Requirements of an interface between PL and RDBMS:

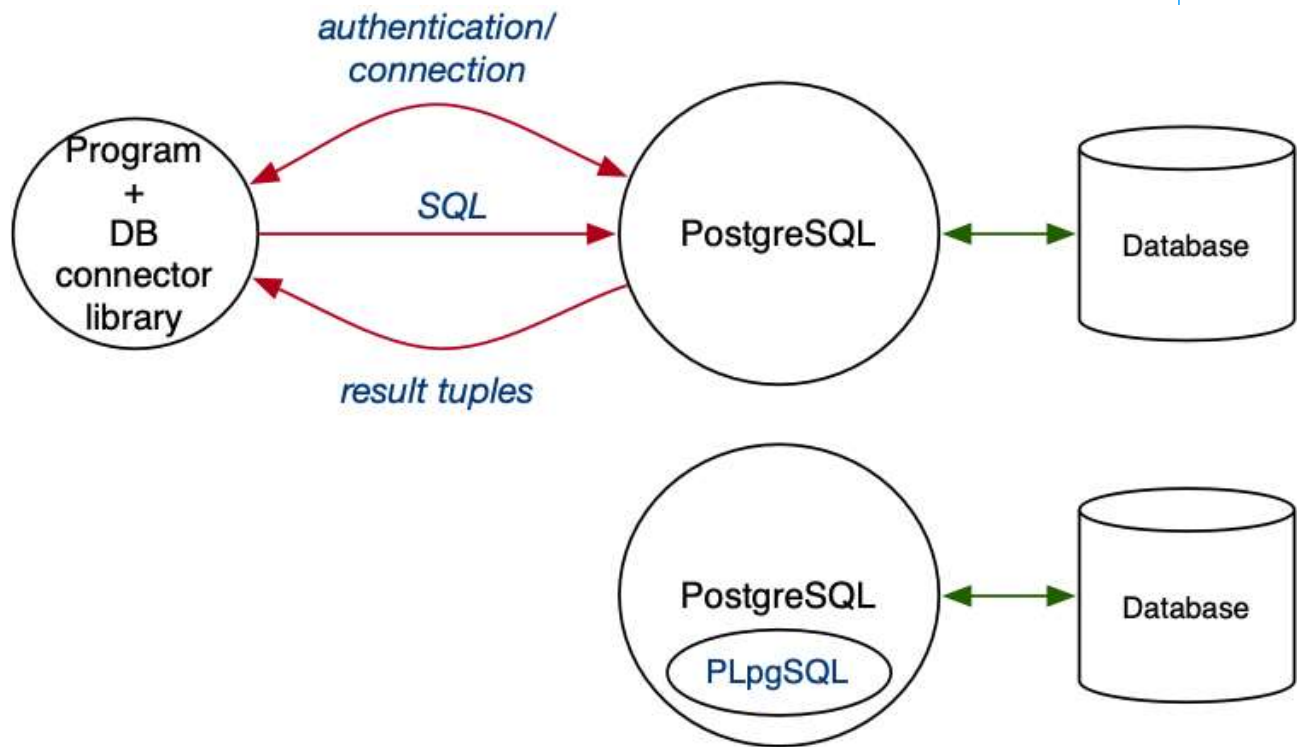

- mechanism for connecting to the DBMS (authentication)
- mechanism for mapping PL "requests" to DB queries
- mechanism for iterating over query results
- mapping between tuples and PL objects

Distance between PL and DBMS is variable, e.g.

- **libpq** allows C programs to use PG structs
- JDBC transmits SQL strings, retrieves tuples-as-objects

❖ Programming with Databases (cont)

Programming Language / DBMS architecture:

COMP3311 20T3 ♦ Programming with Databases ♦ [4/12]

❖ PL/DB Interface

Common DB access API used in programming languages

```
db = connect_to_dbms(DBname, User/Password);  
  
query = build_SQL("SqlStatementTemplate", values);  
  
results = execute_query(db, query);  
  
while (more_tuples_in(results))  
{  
    tuple = fetch_row_from(results);  
    // do something with values in tuple ...  
}
```

This pattern is used in many different libraries:

- Java/JDBC, PHP/PDO, Perl/DBI, Python/Psycopg2, Tcl, ...

❖ PL/DB Interface (cont)

DB access libraries have similar overall structure.

But differ in the details:

- whether object-oriented or procedural flavour
- function/method names and parameters
- how to get data from program into SQL statements
- how to get data from tuples into program variables

Object-relational mappers (ORMs) ...

- aim to hide the details of the database schema and queries
- allow programmers to manipulate objects, not tuples
- potentially use the PLDB connection inefficiently

❖ PL/DB Mismatch

There is a tension between PLs and DBMSs

- DBMSs deal very efficiently with large sets of tuples
- PLs encourage dealing with single tuples/objects

If not handled carefully, can lead to inefficient use of DB.

Note: relative costs of DB access operations from PL:

- establishing a DBMS connection ... very high
- initiating an SQL query ... high
- accessing individual tuple ... small

❖ PL/DB Mismatch (cont)

Consider this (imaginary) PL/DBMS access method:

```
-- establish connection to DBMS
db = dbAccess("DB");
query = "select a,b from R,S where ... ";
-- invoke query and get handle to result set
results = dbQuery(db, query);
-- for each tuple in result set
while (tuple = dbNext(results)) {
    -- process next tuple
    process(tuple['a'], tuple['b']);
}
```

Estimated costs: **dbAccess** = 500ms, **dbQuery** = 200ms, **dbNext** = 10ms

In later cost estimates, ignore **dbAccess** ... same base cost for all examples

❖ PL/DB Mismatch (cont)

Example: find mature-age students (e.g. 10000 students, 500 over 40)

```
query = "select * from Student";
results = dbQuery(db, query);
while (tuple = dbNext(results)) {
    if (tuple['age'] >= 40) {
        -- process mature-age student
    }
}
```

We transfer 10000 tuples from DB, 9500 are irrelevant

Cost = $1 \cdot 200 + 10000 \cdot 10 = 100200\text{ms} = 100\text{s}$

❖ PL/DB Mismatch (cont)

E.g. should be implemented as:

```
query = "select * from Student where age >= 40";
results = dbQuery(db, query);
while (tuple = dbNext(results)) {
    -- process mature-age student
}
```

Transfers only the 500 tuples that are needed.

Cost = $1 \cdot 200 + 500 \cdot 10 = 5200\text{ms} = 5\text{s}$

❖ PL/DB Mismatch (cont)

Example: find info about all marks for all students

```
query1 = "select id,name from Student";
res1 = dbQuery(db, query1);
while (tuple1 = dbNext(res1)) {
    query2 = "select course,mark from Marks"
            + " where student = " + tuple1['id'];
    res2 = dbQuery(db,query2);
    while (tuple2 = dbNext(res2)) {
        -- process student/course/mark info
    }
}
```

E.g. 10000 students, each with 8 marks, \Rightarrow run 10001 queries

Cost = $10001 \times 200 + 80000 \times 10 = 2800s = 46min$

❖ PL/DB Mismatch (cont)

E.g. should be implemented as:

```
query = "select id,name,course,mark"
      + " from Student s join Marks m "
      + " on (s.id=m.student)"
results = dbQuery(db, query);
while (tuple = dbNext(results)) {
    -- process student/course/mark info
}
```

We invoke 1 query, and transfer same number of tuples.

Cost = $1 \cdot 200\text{ms} + 80000 \cdot 10\text{ms} = 800\text{s} = 13\text{min}$
