Limitations of Basic SQL

What we have seen of SQL so far:

- data definition language (create table(...))
- constraints (domain, key, referential integrity)
- query language (select...from...where...)
- views (give names to SQL queries)

This provides powerful declarative data extraction mechanisms.

This is not sufficient to write complete applications.

More extensibility and programmability are needed.

COMP3311 20T3 ♦ Stored Procedures ♦ [1/14]

Extending SQL

Ways in which standard SQL might be extended:

- new data types (incl. constraints, I/O, indexes, ...)
- object-orientation
- more powerful constraint checking
- packaging/parameterizing queries
- more functions/aggregates for use in queries
- event-based triggered actions

All are required to assist in application development.

But still do not provide a solution to developing applications.

COMP3311 20T3 ♦ Stored Procedures ♦ [2/14]

<<

SQL as a Programming Language

At some point in developing complete database applications

- we need to implement user interactions
- we need to control sequences of database operations
- we need to process query results in complex ways
- we need to build a web interface for users to access data

and SQL cannot do any of these.

SQL cannot even do something as simple as factorial!

Ok ... so PostgreSQL added a factorial operator ... but it's non-standard.

COMP3311 20T3 ♦ Stored Procedures ♦ [3/14]

SQL as a Programming Language (cont)

Consider the problem of withdrawal from a bank account:

If a bank customer attempts to withdraw more funds than they have in their account, then indicate "Insufficient Funds", otherwise update the account

An attempt to implement this in SQL:

```
select 'Insufficient Funds'
from Accounts
where acctNo = AcctNum and balance < Amount;
update Accounts
set balance = balance - Amount
where acctNo = AcctNum and balance >= Amount;
select 'New balance: '||balance
from Accounts
where acctNo = AcctNum;
```

COMP3311 20T3 ♦ Stored Procedures ♦ [4/14]

SQL as a Programming Language (cont)

Two possible evaluation scenarios:

- displays "Insufficient Funds", UPDATE has no effect, displays unchanged balance
- UPDATE occurs as required, displays changed balance

Some problems:

- SQL doesn't allow parameterisation (e.g. AcctNum)
- always attempts **UPDATE**, even when it knows it's invalid
- need to evaluate (balance < Amount) test twice
- always displays balance, even when not changed

To accurately express the "business logic", we need facilities like conditional execution and parameter passing.

COMP3311 20T3 ♦ Stored Procedures ♦ [5/14]

Database Programming

Database programming requires a combination of

- manipulation of data in DB (via \$QL)
- conventional programming (via procedural code)

This combination is realised in a number of ways:

- passing SQL commands via a "call-level" interface
 (prog lang is decoupled from DBMS; most flexible; e.g. Java/JDBC,
 PHP, Python)
- embedding SQL into augmented programming
 languages
 (requires pre-processor for language; typically DBMS-specific; e.g. SQL/C)
- special-purpose programming languages in the DBMS
 (closely integrated with DBMS; enable extensibility; e.g. PL/SQL,
 PLpgSQL)

Here we focus on the last: extending DBMS capabilities via programs stored in the DB

COMP3311 20T3 ♦ Stored Procedures ♦ [6/14]

❖ Database Programming (cont)

Combining SQL and procedural code solves the "withdrawal" problem:

```
create function
    withdraw(acctNum text, amount integer) returns text
declare bal integer;
begin
    set bal = (select balance
               from Accounts
               where acctNo = acctNum);
    if (bal < amount) then</pre>
        return 'Insufficient Funds';
    else
        update Accounts
            balance = balance - amount
        where acctNo = acctNum;
        set bal = (select balance
                   from
                          Accounts
                   where acctNo = acctNum);
        return 'New Balance: ' | bal;
    end if
end;
```

(This example is actually a stored procedure, using SQL/PSM syntax)

COMP3311 20T3 ♦ Stored Procedures ♦ [7/14]

<< / >>

Stored Procedures

Stored procedures are small programs ...

- stored in the database, alongside the stored data
- invoked in SQL queries, or automatically invoked in triggers

SQL/PSM is a standard for stored procedures, developed in 1996.

By then, most DBMSs had their own stored procedure languages.

PostgreSQL supports stored procedures in a variety of languages

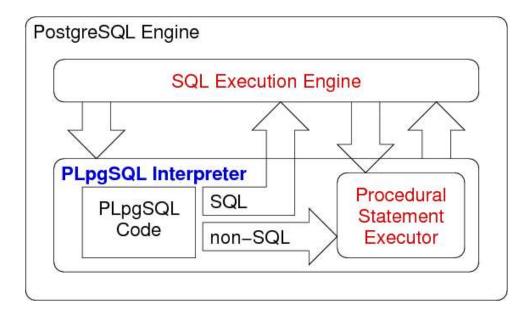

- PLpgSQL ... PostgreSQL-specific procedural language (cf. Oracle's PL/SQL)
- SQL ... functions that resemble parameterised views
- Python, Perl, Tcl, ... etc.

COMP3311 20T3 ♦ Stored Procedures ♦ [8/14]

Stored Procedures (cont)

The PLpgSQL interpreter

- executes procedural code and manages variables
- calls PostgreSQL engine to evaluate SQL statements

Embedded in DBMS engine, so efficient to execute with queries

COMP3311 20T3 ♦ Stored Procedures ♦ [9/14]

SQL Functions

PostgreSQL allows functions to be defined in SQL

```
CREATE OR REPLACE
   funcName(arg1type, arg2type, ....)
   RETURNS rettype
AS $$
   SQL statements
$$ LANGUAGE sql;
```

Within the function, arguments are accessed as \$1, \$2, ...

Return value: result of the last SQL statement.

rettype can be any PostgreSQL data type (incl tuples,tables).

Function returning a table: returns setof TupleType

Details: PostgreSQL Documentation, Section 37.5

COMP3311 20T3 ♦ Stored Procedures ♦ [10/14]

<<

❖ SQL Functions (cont)

Example: info about bars from a given suburb

```
create or replace function
    hotelsIn(text) returns setof Bars
as $$
select * from Bars where addr = $1;
$$ language sql;
-- usage examples
select * from hotelsIn('The Rocks');
                     addr
 Australia Hotel | The Rocks |
                                123456
 Lord Nelson
                 The Rocks
                                123888
select * from hotelsIn('Randwick');
                 addr
                        license
 Royal Hotel | Randwick |
                           938500
```

COMP3311 20T3 \$\langle\$ Stored Procedures \$\langle\$ [11/14]

❖ SQL Functions (cont)

Example: Name of cheapest beer at each bar

Could be implemted by defining an SQL function LowestPriceAt(bar)

```
create or replace
    function LowestPriceAt(text) returns float
as $$
select min(price) from Sells where bar = $1;
$$ language sql;
select * from Sells where price = LowestPriceAt(bar);
```

COMP3311 20T3 ♦ Stored Procedures ♦ [12/14]

<< \ \ >>

Functions vs Views

A parameterless function behaves similar to a view

```
E.g.
```

mydb=# select * from EmpList;
